ABSTRACT

A computer model which simulates the traffic flow of a Navy port has been developed. The model causes a ship to be placed in one of seven possible states: on extended operations, in overhaul, at a tender, in port on normal operations, in port preparing for overseas movement, in port on 30-day stand-down, or on short deployment on normal operations. Hotel utilities, which include steam and electric power, can be provided to a ship in port. A Monte Carlo method is used to determine the length of stay in any state. The model attempts to berth ships coming into port according to a pier-preference scheme. Input to the model includes a description of a ship and its cycle times, and a description of the pier in terms of its utilities and the ships it can berth. Computer output includes a summary of the time each ship spends in each state. The summary can be produced daily, quarterly, or for the entire simulation time of the run, which may be up to six years.

ADMINISTRATIVE INFORMATION

Model analysis and programming were performed by the Logistics Analysis Group of the Operations Research Division with programming assistance from the Program Analysis Group of the Computer-Aided Design Division. The work was funded by the Naval Facilities Engineering Command with O&MN funds.

1. INTRODUCTION

A Port Simulation Model was developed by the Systems Analysis Division (Code 201) of the Naval Facilities Engineering Command (NAVFAC) to help support the OPNAV 1968-69 Pier and Utility Study (Cold Iron Program). This model was later modified to accommodate the updated Cold Iron Study objectives.¹ In April 1971, the Systems Analysis Division requested that the Operations Research Division (Code 186) of the Naval Ship Research and Development Center (NAVSHIPRANDCEN) provide programming assistance for major modifications of this model.

After a thorough analysis of the model, members of the Operations Research Division working in conjunction with the Program Development Group (Code 1856, NAVSHIPRANDCEN), determined that the required modifications to the model were so extensive that a redesign of the model was required. This was accomplished and the computer simulation program was completed by December 1971. This report documents the revised simulation program.

Section 2 of the report presents a model description; Section 3 describes the model operation. Input and output are discussed in Sections 4 and 5 respectively. Section 6 provides recommendations for future development.

A program listing is provided in Appendix A; Appendix B presents the major arrays of the system. Sample input and output are shown in Appendixes C and D respectively.

1 "Update of the Cold Iron Program Study," Naval Facilities Engineering Command, Facilities Planning Group, Systems Analysis Division, NAVFAC Code 201, Study No. 108, 15 March 1971. (Study performed by Andrew J. Vero, LTJG Robert J. Kidder, Eloy R. Villa, Peter T. Bidwell, and Wendy A. Budd.)

2. MODEL DESCRIPTION

2.1 The System

The mathematical model is designed to simulate the flow of ship traffic in a port, given a description of the demands of each ship in the system on the port and the ability of the port to handle them. A summary of the traffic load, and how it affects each ship, is presented as computer output.

The model depicts seven states of Naval ship operation and is structured as a closed-system queuing process with limited facilities in some of the states. This generalized structure is used to analyze the effect of an increase or decrease in facilities on the operation of a port. A simulation model has been formulated so that the configuration of homeported ships for each port can be tested against a stated ship-deployment policy.

Each ship in the system must be in one of the following seven states: (1) on extended operations, (2) conducting normal operations in port, (3) conducting normal operations out of port, (4) in shipyard maintenance, (5) undergoing maintenance at a tender, (6) in priority cold iron, preparing for overseas movement (POM), (7) in priority cold iron returned from overseas extended operations (30-day stand-down). If a ship is waiting for berthing or utilities to become available for one of the last four states, then it is considered to be in state 2. Cold-iron status is defined as a condition in which the ship is provided with utility services from land sources so that it can shut down all boilers and utility generating equipment. The distribution of all ships among the seven states describes the condition of the port.

The system is represented in computer storage by a set of four major tables which contain information on each ship in the system. These tables are defined in Appendix B. They include (1) the ship's

state and the time remaining for the ship in that state, (2) the time remaining until the ship is permitted to enter either the POM or extended operation state, (3) the time remaining until the ship is permitted to enter the shipyard maintenance state, and (4) the time remaining until the ship is permitted to enter a tender maintenance state. A clock with a fixed time increment of one day is used to time the simulation. Each day the table is checked to determine which ships have completed the times remaining in their current states. Upon completion of its time in a state, a ship is moved through the system according to the diagrams in Figures 1 and 2. When a ship leaving one state may enter one of several other states, the state entered is determined according to a hierarchy, as explained in Section 3. The amount of time spent in a shipyard for overhaul, the time between overhauls, the time spent on extended operations, and the time periods of extended operation are obtained by selecting a sample via Monte Carlo methods from suitable normal distributions. The time remaining prior to tender maintenance at the beginning of each quarter is determined by a uniform distribution. These distributions are discussed in Section 3.1.

Figure 1 - Structure of the Queuing System

(Note: Regardless of the above flow pattern, the model considers a ship that is waiting for pier or utility accommodations to be in state 2, "normal operations in port.")

Figure 2 - Flow Diagram of the Queuing System

2.2 The Ships

Identification information and ship characteristics for each ship homeported in the port under study are stored in a table within the computer. The ship characteristics include:

- an index to indicate the ship type
- the amount of electric current and steam that the ship may furnish, if the ship is a tender
- the amount of electric current and steam that it requires for a cold-iron stand-down
- the number of frames* needed to berth it
- the number of ships that may nest next to it, if any
- the number of days per quarter that it may spend at a tender, if any (usually two or three weeks; i.e., 14 or 21 days)
- the mean and standard deviation in days for the time between overhauls
- the mean and standard deviation in days for the time in overhaul
- the mean and standard deviation in days for the time between extended operations
- the mean and standard deviation in days for time on extended operations.

A "class" designation for tenders is also included. (see Section 3.2).

Ship types are indicated by the indexing scheme given in Table 1. This indexing scheme is used to indicate the types of ships that can occupy the same berthing positions.

* In discussing docks, a "frame" is 100 feet of berthing space alongside the dock.

2.3 Frame and Pier Description

Each pier in the port is described by a table in the computer memory containing the amount of electric power and steam available at that pier and the amount of electric power and steam in use at that pier.

The pier is described more specifically by a table containing information about each of its frames. This table includes:

- the status of the frame; i.e., occupied or empty
- the amount of electric power and steam available
- the number of ships that can nest against it
- the position of the frame in relation to the pier; i.e., at the beginning, at the end, or in between
- the pier number
- the ship types which can berth at the frame (a maximum of five separate ship indexes, ordered into five preferences as explained in Section 2.5)

If the frame is occupied, the following information is also included:

- the amount of electric power and steam in use
- the ship berthed pierside and the number of ships nested against it, if any

If less than five ship types can berth at a given frame, a frame preference index of 99 specifies that the frame will berth no other ships than those already specified, if any.

2.4 Berthing Protocol

Ships receive priority berthing if they are either preparing for overseas movement or returning from extended overseas operations. In the first case, they must receive a 21-day period in cold iron for preparatory maintenance; in the second, they must receive at least 30 days cold iron for ship maintenance and crew leave.

A ship can be berthed at pierside and provided with no utilities (steam and electric power), partial utilities, or full utilities (cold iron). Similarly it can be in one of these three conditions while nested to another ship, or it can be anchored in the stream while awaiting berthing.

In the model, as ships enter the port for berthing during the simulated day, they enter an arrival queue and are not berthed immediately. After all ships have been processed; i.e., all newly arrived ships are in the arrival queue, the model (1) attempts to provide utilities to those ships already in berths which still need them, (2) attempts to berth the ships still needing berthing, and (3) once a ship is berthed, attempts to provide utilities. Immediately eliminated from consideration for utilities are all ships which are expected to remain in port less than three days and all tenders supplying utilities. Initially considered are all ships occupying a berth and in a priority state; i.e., preparing for overseas movement or returned from extended operations. Following this, the rest of the berthed ships are considered.

After the berthed ships have been taken into account, ships in the stream and new arrivals are considered. First an attempt is made to berth priority ships waiting in the stream, then priority ships among the new arrivals, then the remaining ships waiting in the stream, and finally the remaining new arrivals.

Although ships preparing for overseas movement or returning from extended operations are given priority status for berthing and utilities, there is also an inherent priority among ships with the same defined priority (both have priority or neither has priority).

This results from the manner in which the information defining the ships is read-in and stored in the computer. If ships A and B both need utilities or can occupy the same berth, and if the information defining ship A was read into the computer before the information defining ship B, and if neither has defined priority over the other and both are in the same state (i.e., both in stream, both new arrivals, or both needing utilities), ship A is always serviced before ship B, regardless of type or class.

2.5 Berthing Implementation

If the ship index is not 15, 29, 30, 31, 36, 37, 38, or 39; i.e., if the ship is not an AGSS, AGS, CGN, CC, CAG, CG, CA, CLG, DXGN, DXG, DDG, DD, DDE, DLGN, DLG, DL, DEG, DE, SS, SSBN, or SSN, then the berthing is implemented according to paragraph 2.5.1. If the ship is one of those listed above, the berthing implementation is slightly different, as discussed in paragraph 2.5.2.

2.5.1. For ships other than those listed above, an attempt is made to place the ship at a first-preference berth (i.e., a berth whose frames are assigned as first preference the specific index describing that ship type, see Table 4), pierside with full utilities (unless the ship is a tender returning from shipyard maintenance, in which case it will be berthed at a first-preference berth with no utilities). The attempt is made starting at the first frame and continuing in order to the last frame. If full utilities are not available and the ship will be in port for less than three days, then the ship is berthed at a first-preference berth without utilities. If no first-preference berth is available with full utilities, and if the ship does not require priority berthing, then an attempt is made to berth the ship at a first-preference berth without utilities.

If no first-preference berth is available and the ship is a tender, then first-preference berthing is reserved for it. No other ships can berth at that berth until the tender is berthed. In other

cases, an attempt is made to berth the ship at any other allowed berth with utilities. For ships of these types, frames with the four other "preferences" are considered by frame serial number with no order of preference. If no berthing with utilities is available, an attempt is made to berth the ship without utilities.

If no pierside berthing is available, an attempt is made to nest the ship with full utilities, treating the five frame preferences by frame serial number without regard to order. If this cannot be done, an attempt is made to nest the ship with no utilities. If this fails, then the ship is placed in the stream.

2.5.2. If the ship index is one of those eight cited at the beginning of Section 2.5, then the berthing implementation is slightly modified. The order of the berthing attempts is:

- (1) first-preference pierside with full utilities
- (2) first-preference nested with full utilities
- (3) second-preference pierside with full utilities
- (4) second-preference nested with full utilities
- (5) first-preference pierside without utilities
- (6) first-preference nested without utilities
- (7) second-preference pierside without utilities
- (8) second-preference nested without utilities.

For a ship that will be in port less than three days, the first available allowable berth is selected, according to the above scheme, but as noted previously, the ship is given no utilities. If no berth is available according to the above scheme, then berthing protocol is the same as in paragraph 2.5.1.

3. MODEL OPERATION

3.1 Distributions

The times a ship spends in overhaul, between overhauls, on extended operations, and between extended operations are obtained by means of a sample from a normal distribution. Given a mean μ and a standard deviation σ , a sample value S from a normal distribution can be approximated by

$$S = \mu + \sigma * \sum_{i=1}^{12} (R_i - \frac{1}{2})$$

where R_i are independent random numbers between zero and one.²

At the beginning of each quarter, the time remaining before a ship requires tender maintenance for that quarter (91 days) is calculated from a uniform distribution, i.e.,

$$T = R * 91$$

where T is the time remaining before a ship requires tender maintenance and R is a random number between zero and one. If the ship was tied up to a tender at the beginning of a quarter, or if a ship returned from extended operations or from shipyard maintenance during the quarter, it is assumed to require no tender maintenance for that quarter. The time spent at a tender is either two or three weeks as specified in the input data. The distributions were selected because they approximated reality. NAVFAC provided the means and standard deviations for each distribution for each ship, based on previous observations and an analysis of the port logs. Examples of these means and standard deviations are provided as part of the sample input in Appendix C.

On the basis of a seven-day week, the probability that a ship will be in port for the weekend is 0.9, and the probability that it will be out is 0.1. If the ship is to be in port for the weekend,

2. Hammersley, J.M., and Handscomb, D.C., Monte Carlo Methods, Barnes & Noble, Inc., New York, 1964, pp 39-40.

then the number of days out is calculated by random-number selection from a uniform distribution which varies according to the day of the week on which the ship is going out. If the ship is to depart on Monday, the values range from one to four days. If the ship is to depart on Tuesday, the values range from one to three days, etc. If the ship is to be out for the weekend, then the number of days out is calculated by random-number selection from a uniform distribution which again varies according to the departure day. If the ship is to depart on Monday, the values range from seven to 11 days. If the ship is to depart on Tuesday, the values range from seven to ten days, etc.

A ship coming into port during the week will remain there for the weekend. Its departure day the next week is calculated by random-number selection from a uniform distribution over the following Monday to the following Thursday.

3.2 Initialization

Prior to the beginning of the simulation, the system is initialized by placing each ship in one of the system states by a Monte Carlo method, as explained below. The baseline distribution of the ships in the system was determined by NAVFAC, and is based on an analysis of port control logs. The baseline distribution is as follows: initially one-third of the ships are on extended operations and two-thirds on normal operations or in port. The ships on normal operations or in port (66% of all ships) are further divided as follows: 8% (of all the ships) are in overhaul, 5% are in priority cold iron preparing for overseas movement, 5% are in priority cold iron for 30-day stand-down, 4.8% are on short deployment, and the remaining 43.2% are in port requiring normal berthing. The distribution of the last 48% is obtained by assuming day zero to be Sunday, hence 10% of the ships are out of port on normal operations and 90% are in port.

The initialization of the program is implemented by selecting a random number and comparing it to the baseline distribution for each ship. For example, if the random number R satisfied $0 \leq R \leq .08$, the ship was placed in overhaul; if $.08 < R \leq .13$, the ship was placed on POM, etc. No ships are initially tied up to a tender.

The values for the tables specifying the times remaining until a ship goes on extended operations, into overhaul, or to a tender are initialized for the time remaining until extended operations as follows: for each ship, a sample value is taken from the appropriate normal distribution. (See Appendix C for examples.) Then 21 days are subtracted from this value to allow time for preparing for overseas movement. (The same effect could be obtained by subtracting 21 from the mean when it is stored in the ship characteristics table.) This sample value is then initialized by multiplying it by a random number between 0 and 1. The sample value represents the original calculated value. "Initializing" it by multiplying it by a random number is required to simulate calculating the sample at a random past time. For the time remaining until overhaul for each ship, a similar sample value is taken from the appropriate normal distribution and is initialized. If the ship is on normal operations and not in overhaul or priority cold iron, it will go to a tender during the quarter if an appropriate tender is available. In this case, the 90-day period is multiplied by a random number, rounded to the next highest integer, and stored in a table.

The number of days remaining in each initial state is similarly initialized as follows: for ships on extended operations or in overhaul, a sample value is taken from the normal distribution specifying the duration of stay in that state and is then multiplied by a random number between 0 and 1. If the ship is in priority cold iron, the 30- or 21-day value is similarly initialized for the time required to return from 30-day stand-down or to prepare for overseas movement.

If the ship is out on normal operations, its return to the port during the week is equally probable for each day, and the day of its return is calculated by dividing a random number between 0 and 1 by 0.2 and rounding to the next highest integer. If the ship is in port on day zero, it will be ready to depart on one of the next four days (i.e., Monday through Thursday, since the ship will not depart from the port on Friday, Saturday, or Sunday). The day of its departure is calculated by dividing a random number by 0.25 and rounding to the next highest integer. The calculated time is rounded upward in each case by adding 1 and truncating.

Tenders represent a special case. A tender whose "class" designation (program terminology, not to be confused with normal ship class designations; see Section 4) begins with a 2 (e.g., 2.1) will not go on extended operations at all; a tender whose class designation begins with a 1 will deploy. The class designations are used to prevent all tenders of the same class from being away from the port at the same time and thus leaving no tenders to provide maintenance. Only the right side of the decimal is compared, so that tenders with class designations 2.1 and 1.1 are considered the same except for deployment. All tenders will remain in port when on normal operations, except when in overhaul. All tenders can perform maintenance when on normal operations, except when in priority cold iron or in overhaul.

3.3 Daily Ship State Changes

At the beginning of each day, the tables designating for each ship the time remaining in the present state, the time remaining in normal operations, the time until tender maintenance is required, and the time remaining until overhaul, are decremented (reduced by 1) for each ship. If the time remaining for a ship in its present state is not zero after the decrementing, no state change is made, regardless of the values of the other tables, which therefore may now be negative.

The daily state changes follow the structure shown previously in Figure 1. If a ship may enter more than one state, the states have the following hierarchy: overhaul, POM or extended operations, tender maintenance, and lastly, normal operations. Monte Carlo methods are used to determine which of two states with equal priority is chosen; i.e., in or out of port for normal operations.

A ship returning from extended operations is placed in the arrival queue with a priority status. This is implemented by effectively adding 100 to its ship index. When implementing the berthing operation, a ship whose index is greater than 100 has priority. A sample value is taken from the normal distribution for the amount of time to be spent in normal operations and stored in the proper table. The value in the table for the time remaining until tender maintenance is required is reset so that the ship will not go to a tender during the present quarter.

A ship in a normal operations cycle in port may go to a shipyard, to POM, to a tender, or on a short deployment out of the port. It will go to a shipyard if the value specifying the time to go to a shipyard is less than or equal to zero.* In this case, the ship releases its berth and utilities, if it has any, and is considered to be in the shipyard. The duration of its stay is determined by a sample from the corresponding normal distribution.

If the ship is not going to a shipyard and the value specifying the time remaining before the ship goes on extended operations is less than or equal to zero, the ship will go to POM. If it has a berth which can provide adequate utilities, the ship is given priority status and remains in its berth. The priority status is implemented by adding 200 to the ship index. If the utilities are not then available, it

* Note: Values of time remaining before the ship goes to a shipyard (tender or POM) selected from the appropriate normal distribution as described above are always greater than zero. Nevertheless, such times will usually be overexpended and hence go negative, since the program will not change states until the time for a ship to remain in its present state is zero.

waits for them. If its berth cannot provide adequate utilities, the ship releases its berth, is given priority status, and is placed in the arrival queue. It is similarly given priority status if it is waiting in the stream.

If the ship is not going to the shipyard or POM, and if the value for the time to go to the tender is less than or equal to zero, a check is made to see if a tender in service can service the ship. If not, the ship ignores going to the tender during this particular quarter and will go on a short deployment out of port. If a tender is available, a check is made to see if there is room for the ship. If not, the ship remains in its present position waiting for the tender to become available and continues using pier utilities or continues waiting in the stream. If the ship can go to the tender, it releases its berth and utilities, if it has any, and immediately goes to the tender for two or three weeks, as specified in the ship table discussed earlier.

If the ship is to go to none of these three states, it goes out on a short deployment and releases its berth and utilities, if it had any. The duration of its stay out of port depends on the departure day as already explained.

A ship on normal operations returning from a short deployment goes through a similar process, except that it has no berth or utilities to give up. If it is not going to a shipyard or tender, it is placed in the arrival queue and is given priority status if entering POM. It will stay in port, if it is not going to a shipyard, a tender, or to POM, until the following week, and will depart on one of four days, as explained earlier.

A ship coming out of shipyard maintenance will go directly on extended operations if the value in that time-remaining table is less than or equal to zero, or it may go on a short deployment out of port, or it may be placed in the arrival queue for berthing according to a random number selection. A new sample is selected from the normal distribution for the time remaining until the next overhaul and stored in the correct table.

A ship coming out of 30-day stand-down (priority cold-iron maintenance required at the completion of extended operations) is similar to a ship on normal operations in port, and may continue in cold iron. Alternatively, it may go out on a short deployment or it may go to a shipyard, thereby releasing its berth and its utilities. The ship will remain in port in cold iron if the 30-day period ends on a Friday, Saturday, or Sunday. It will not go to a tender during the present quarter.

A ship coming out of POM goes directly on extended operations and releases its berth and utilities. The time of deployment is selected from the normal distribution as specified in the ship table discussed earlier.

A ship at a tender can go to a shipyard, on extended operations, or on normal operations deployment. If it is to go on extended operations, it will remain at the tender for a total of three weeks, regardless of the time specified for tender maintenance in the ship table. Otherwise it will release its berth and utilities and go either to a shipyard or on a short deployment.

After all incoming ships have been processed and all outgoing ships have released their berths, utilities are given to those ships berthed with inadequate utilities (no utilities or less than the ship requires), if utilities are available. The ships in the stream or in the arrival queue are berthed as defined earlier.

At the end of a quarter, new times for ships to wait for tender maintenance are calculated.

4. INPUT

Input to the Port Berthing Simulation program consists of a control card, a set of frame-definition cards, and a set of pier-definition cards.

The control card contains information defining the simulation run and specifying the print options, as shown in Table 2.

TABLE 2 - CONTROL CARD FORMAT

<u>Col</u>	<u>Variable Name</u>	<u>Remarks</u>
1-3	K1	Number of ships
4-6	K2	Number of frames
7-9	K3	Number of piers
10-11	NQ	Number of quarters program is to run (maximum of 24)
12	IJ1	Print Option 0 = Selective printing of daily reports, as determined by IJ6, IJ7, and IJ9 1 = Print all daily reports. If no daily reports are desired, leave card columns 12-34 and column 36 blank.
13-16	IJ2	Day to start initial printing of daily reports (if any)
17-20	I2J	Number of days to print initially
21-24	IJ3	Number of days to skip printing after initial printing
25-28	IJ4	Number of days to print after the count specified by IJ3 or I4J is reached.
29-32	I4J	Number of days to skip after the count specified by IJ4 is reached.

(Note: IJ4 and I4J are repeated throughout the remainder of the run. The following report options enable the user to select the reports printed, depending on settings of above variables.)

Table 2 (continued)

<u>Col</u>	<u>Variable Name</u>	<u>Remarks</u>
33	IJ6	0 = No printing of HSHIP matrix report 1 = HSHIP matrix printed if day is to have printing
34	IJ7	0 = No printing of frame matrix 1 = Printing of frame matrix if day is to have printing
35	IJ8	0 = No printing of quarterly summary 1 = Printing of quarterly summary
36	IJ9	0 = No printing of port log 1 = Printing of port log
37-52	IPOINT	Name of port (16 alphanumeric characters)

The next set of cards comprises the ship-definition cards which constitute the SHIP Table. These are read-in as shown in Table 3.

TABLE 3 - SHIP CARDS

<u>Col</u>	<u>Definition</u>	<u>Remarks</u>
1-3	Ship number	Assigned in sequential order in the ship matrix.
4-7	Ship type	Up to 4 alphanumeric characters
8-9	Sequence number	= 1 if first ship of type (as specified in card columns 4-7) = 2 if 2nd ship of same type Etc. (1 card per ship)
10-12	Ship classification	= 0 not tender = 1.1, General tender (AR) = 1.2, Sub tender (AS) = 1.3, destroyer or auxiliary tender (AD) = 2.1, 2.2, 2.3, similar to 1.1, 1.2, and 1.3, respectively, except that if the classification is greater than 2, tender leaves port only for shipyard overhaul.
13-16	Mean for duration of normal operations	In months
17-19	Standard deviation for duration of normal operations	In months
20-23	Mean for duration of extended operations	In months
24-26	Standard deviation duration of extended operations	In months
27-30	Mean for duration of overhaul	In months

Table 3 (continued)

<u>Col</u>	<u>Definition</u>	<u>Remarks</u>
31-33	Standard deviation for duration of overhaul	In months
34-37	Mean for time between overhauls	In months
38-40	Standard deviation for time between overhauls	In months
41-44	Days at tender	Generally 14 or 21
45-48	Electric power required	In units of 100 kw
49-52	Steam required	In units of 100 lb/hr
53-54	Frames required	
55	Nesting capability	Number of ships that can nest outside defined ship
56-59	Electric power furnished	Capability if tender (kw)
60-63	Steam furnished	Capability if tender (lb/hr)
64-67	Ship index	See Table 1

The next set of cards comprises the frame-definition cards which specify the FRAME Table. These are read-in as shown in Table 4.

TABLE 4 - FRAME-DEFINITION CARDS

<u>Col</u>	<u>Variable Name</u>	<u>Description</u>
1-3	IA	Frame number
4	FRAME (IA,1)	Availability = 1, available = 2, occupied
5-7	FRAME (IA,2)	Amount of steam available (lb/hr)
8-10	FRAME (IA,3)	Amount of electric power available (kw)
14	FRAME (IA,4)	Number permitted to nest
15-16	FRAME (IA,5)	1st-preference ship index
17-18	FRAME (IA,6)	2nd-preference ship index
19-20	FRAME (IA,7)	3rd-preference ship index
21-22	FRAME (IA,8)	4th-preference ship index
23-24	FRAME (IA,9)	5th-preference ship index
25	FRAME (IA,10)	End of pier code
43-44	FRAME (IA,17)	Pier number

The last set of input cards contains the PIER description data. These are read-in as shown in Table 5.

TABLE 5 - PIER DESCRIPTION CARDS

<u>Col</u>	<u>Name</u>	<u>Description</u>
1-2	IA	Pier number
2-5	PIER (IA, 1)	Total steam available
9-11	PIER (IA, 3)	Amount of electric power available

Sample input is shown in Appendix C.

5. OUTPUT

As data are read in, a validity check is made. If an error in the data is detected, an error message is printed out and the program stops. If no error is detected, a search is made to see if a berth and adequate utilities are available for each ship. If not, a warning message is printed out.

The input data defining the ships and frames are printed out. After the initialization, the frame matrix is again printed out. If no printing is requested on the control card, only the final summary page is printed out. Sample output is shown in Appendix D.

6. RECOMMENDATIONS FOR FUTURE DEVELOPMENT

Production runs of this model have indicated the possibility that ships have on occasion waited overly long for priority cold iron when tied up at a berth which has much nesting. This is a model flaw and should be investigated. The handling of ships waiting for a tender also needs improvement. Currently, these ships remain in their present state while waiting for the tender to become available, and the tender queue has no priority to it. The reservation system for tenders should possibly be changed to move non-priority ships away from the pier to make room for the tender. Rarely should a tender have to wait for a berth.

ACKNOWLEDGMENTS

The author would like to thank Miss Evelyn DeLong for her programming assistance.

APPENDIX A
PROGRAM LISTING

Appendix A contains a listing of the port simulation computer program.

APPENDIX B
MAJOR ARRAYS

Appendix B contains definitions of the components of the major internal computer storage arrays.

MAJOR ARRAYS

1. SHIP (N, 1) = Ship number
 SHIP (N, 2) = Ship name
 SHIP (N, 3) = Sequence number
 SHIP (N, 4) = Ship class if tender
 SHIP (N, 5) = Mean for time between extended operations
 SHIP (N, 6) = Standard deviation for time between extended operations
 SHIP (N, 7) = Mean for time on extended operations
 SHIP (N, 8) = Standard deviation for time on extended operations
 SHIP (N, 9) = Mean for time in overhaul
 SHIP (N, 10) = Standard deviation for time in overhaul
 SHIP (N, 11) = Mean for time between overhauls
 SHIP (N, 12) = Standard deviation for time between overhauls
 SHIP (N, 13) = Days at tender per quarter
 SHIP (N, 14) = AC Power required
 SHIP (N, 15) = Frames required
 SHIP (N, 16) = Steam required
 SHIP (N, 17) = Number of ships which can nest outside ship
 SHIP (N, 18) = AC Power furnishing capability (if tender)
 SHIP (N, 19) = Steam furnishing capability (if tender)
 SHIP (N, 20) = Index
 SHIP (N, 21) = Steam being used (temporary storage)
 SHIP (N, 22) = Electric power being used (temporary storage)

2. HSHIP (N, 1) = Ship number
 HSHIP (N, 2) = Port status
 1 = In port
 2 = Out of port
 HSHIP (N, 3) = Duration of stay in present status

HSHIP (N, 4) = In port status

0 = Not in port

1 = Cold iron-pierside

2 = Not used

3 = Partial utilities-pierside

4 = No utilities-pierside

5 = Cold iron-nested at pier

6 = Partial utilities-nested at pier

7 = No utilities-nested at pier

8 = At tender

9 = Not used

10 = Not used

11 = In stream

12 = In overhaul

HSHIP (N, 5) = Highest frame occupied by ship

HSHIP (N, 6) = Present state

1 = Extended operations

2 = Normal operations (weekly cycle)

3 = Overhaul

4 = 30-day stand-down

5 = POM

6 = Tender supplying utilities

3. FRAME (N, 1) = Frame status

1 = Available

2 = Occupied

FRAME (N, 2) = Steam capability

FRAME (N, 3) = AC Power capability

FRAME (N, 4) = Number permitted to nest

FRAME (N, 5) = Index of ship which is 1st preference in berth

FRAME (N, 6) = Index of ship which is 2nd preference in berth

FRAME (N, 7) = Index of ship which is 3rd preference in berth

FRAME (N, 8) = Index of ship which is 4th preference in berth

FRAME (N, 9) = Index of ship which is 5th preference in berth

99 = No ship can berth there

FRAME (N, 10) = End of pier code

0 = Frame in middle of pier

1 = Frame at beginning of pier

2 = Frame at end of pier

FRAME (N, 11) = Steam in use

FRAME (N, 12) = AC Power in use

FRAME (N, 13) = Ship number berthed pierside

FRAME (N, 14) = Ship name berthed pierside

FRAME (N, 15) = Ship sequence number berthed pierside

FRAME (N, 16) = Number of ships nested at frame

FRAME (N, 17) = Pier number

4. NODAYS (N, 1) = Number of days remaining until overhaul

NODAYS (N, 2) = Number of days remaining until tender

NODAYS (N, 3) = Number of days remaining until extended operation

APPENDIX C

SAMPLE INPUT

Appendix C contains a listing of the data for a sample run.

8 24 2 11 10 70 11 NEW LONDON TEST

END OF FILE MARKER (6-7-8-9 PUNCH)

APPENDIX D

SAMPLE OUTPUT

Appendix D contains the computer printout produced when using the sample input in Appendix C. Page D-2 is a table of the ships in the model and their characteristics. Page D-3 is a table of the frames in the model and their characteristics. Page D-4 is a table listing the status of each ship in the game on day 1, quarter 1. Page D-5 is a table listing the status of each frame in the game on day 1, quarter 1. Pages D-4 and D-5 can be listed for every day as explained earlier. Page D-6 is a final summary page which can also be produced for each quarter.
